BackPropagation

There will be some functions that start with the word "grader" ex: grader_sigmoid(), grader_forwardprop(), grader_backprop() etc, you should not change those function definition.

Every Grader function has to return True.

Loading data

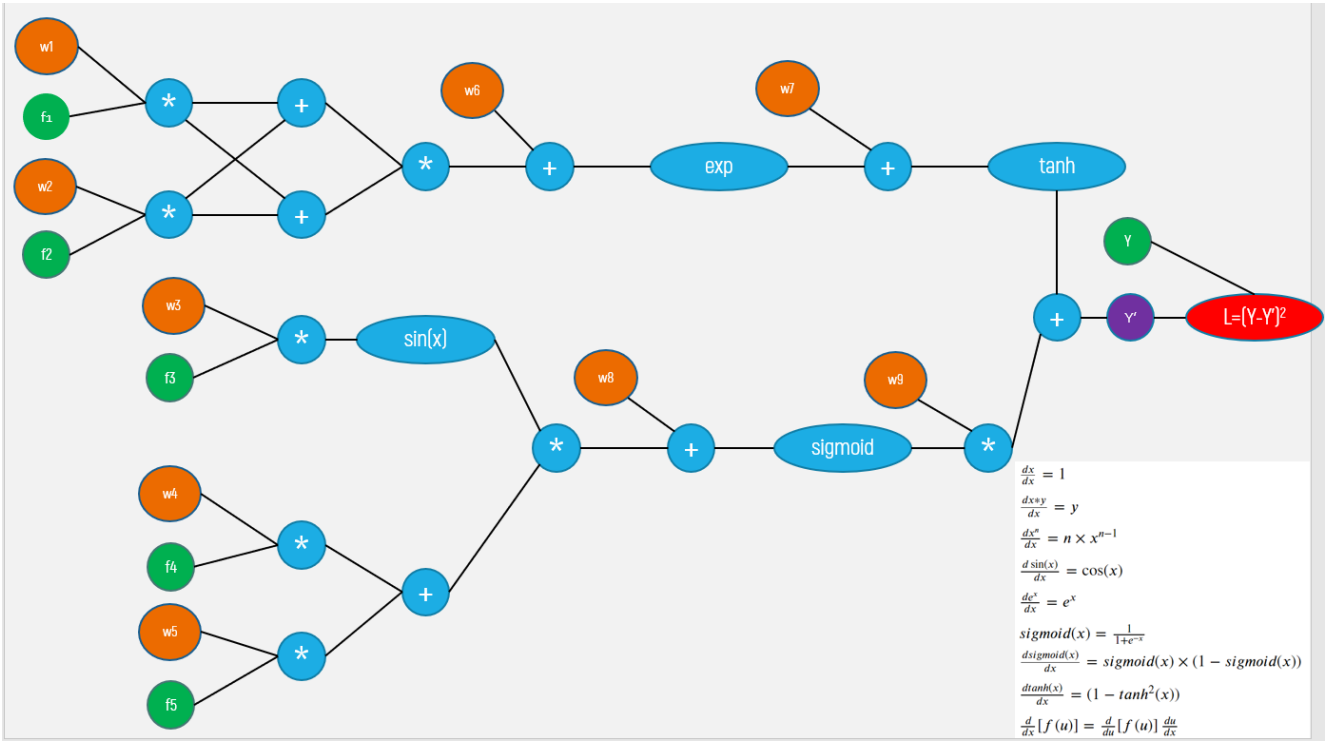
In [1]:

```
import pickle
import numpy as np
from tqdm import tqdm
import matplotlib.pyplot as plt

with open('data.pkl', 'rb') as f:
    data = pickle.load(f)
print(data.shape)
X = data[:, :5]
y = data[:, -1]
print(X.shape, y.shape)
```

```
(506, 6)
(506, 5) (506,)
```

Computational graph



- **If you observe the graph, we are having input features [f1, f2, f3, f4, f5] and 9 weights [w1, w2, w3, w4, w5, w6, w7, w8, w9].**
- **The final output of this graph is a value L which is computed as (Y-Y')^2**

Task 1: Implementing backpropagation and Gradient checking

Task 1: Implementing backpropagation and Gradient checking

Check this video for better understanding of the computational graphs and back propagation

In [2]:

```
from IPython.display import YouTubeVideo
YouTubeVideo('i94OvYb6noo',width="1000",height="500")
```

Out[2]:

Gradient clipping

Check this blog link for more details on Gradient clipping

we know that the derivative of any function is

$$\lim_{\epsilon\to0}\frac{f(x+\epsilon)-f(x-\epsilon)}{2\epsilon}$$

- **The definition above can be used as a numerical approximation of the derivative. Taking an epsilon small enough, the calculated approximation will have an error in the range of epsilon squared.**
- **In other words, if epsilon is 0.001, the approximation will be off by 0.00001.**

Therefore, we can use this to approximate the gradient, and in turn make sure that backpropagation is implemented properly. This forms the basis of gradient checking!

Gradient checking example

lets understand the concept with a simple example: $f(w1,w2,x1,x2)=w_{1}^{2} . x_{1} + w_{2} . x_{2}$
from the above function , lets assume $w_{1}=1$, $w_{2}=2$, $x_{1}=3$, $x_{2}=4$ the gradient of f w.r.t w_{1} is \begin{array} {lcl} \frac{df}{dw_{1}} = dw_{1} &=&2.w_{1}.x_{1} \\& = &2.1.3\\& = &6 \end{array}

let calculate the aproximate gradient of w_{1} as mentinoned in the above formula and considering $\epsilon=0.0001$ \begin{array} {lcl} dw_1^{approx} & = & \frac{f(w1+\epsilon,w2,x1,x2)-f(w1-\epsilon,w2,x1,x2)}{2\epsilon} \\ & = & \frac{((1+0.0001)^{2} . 3 + 2 . 4) - ((1-0.0001)^{2} . 3 + 2 . 4)}{2\epsilon} \\ & = & \frac{(1.00020001 . 3 + 2 . 4) - (0.99980001. 3 + 2 . 4)}{2*0.0001} \\ & = & \frac{(11.00060003) - (10.99940003)}{0.0002}\\ & = & 5.99999999999 \end{array}

. 4)}{2*0.0001} \\ & = & \frac{(11.00060003) - (10.99940003)}{0.0002} \\ & = & 5.999999999999 \end{array}

Then, we apply the following formula for gradient check: *gradient_check* = $\frac{\left\Vert\left (dW-dW^{approx}\rm\right) \right\Vert_2}{\left\Vert\left (dW\rm\right) \right\Vert_2+\left\Vert\left (dW^{approx}\rm\right) \right\Vert_2}$

The equation above is basically the Euclidean distance normalized by the sum of the norm of the vectors. We use normalization in case that one of the vectors is very small. As a value for epsilon, we usually opt for 1e-7. Therefore, if gradient check return a value less than 1e-7, then it means that backpropagation was implemented correctly. Otherwise, there is potentially a mistake in your implementation. If the value exceeds 1e-3, then you are sure that the code is not correct.

in our example: *gradient_check* $ = \frac{(6 - 5.999999999994898)}{(6 + 5.999999999994898)} = 4.2514140356330737e^{-13}$

you can mathamatically derive the same thing like this
\begin{array} {lcl} dw_1^{approx} & = & \frac{f(w1+\epsilon,w2,x1,x2)-f(w1-\epsilon,w2,x1,x2)}{2\epsilon} \\ & = & \frac{((w_{1}+\epsilon)^{2} . x_{1} + w_{2} . x_{2}) - ((w_{1}-\epsilon)^{2} . x_{1} + w_{2} . x_{2})}{2\epsilon} \\ & = & \frac{4. \epsilon.w_{1}. x_{1}}{2\epsilon} \\ & = & 2.w_{1}.x_{1} \end{array}

Implement Gradient checking

(Write your code in def gradient_checking())

Algorithm

Task 2 : Optimizers

- As a part of this task, you will be implementing 3 type of optimizers(methods to update weight)
- Use the same computational graph that was mentioned above to do this task
- Initilze the 9 weights from normal distribution with mean=0 and std=0.01

Check below video and this blog

In [3]:

```
from IPython.display import YouTubeVideo
YouTubeVideo('gYpoJMlgyXA',width="1000",height="500")
```

Out[3]:

Algorithm

```
    for each epoch(1-100):
        for each data point in your data:
            using the functions forward_propagation() and backword_propagation() compute the
gradients of weights
            update the weigts with help of gradients  ex: w1 = w1-learning_rate*dw1
```

Implement below tasks

- **Task 2.1: you will be implementing the above algorithm with Vanilla update of weights**
- **Task 2.2: you will be implementing the above algorithm with Momentum update of weights**
- **Task 2.3: you will be implementing the above algorithm with Adam update of weights**

Note : If you get any assertion error while running grader functions, please print the variables in grader functions and check which variable is returning False .Recheck your logic for that variable .

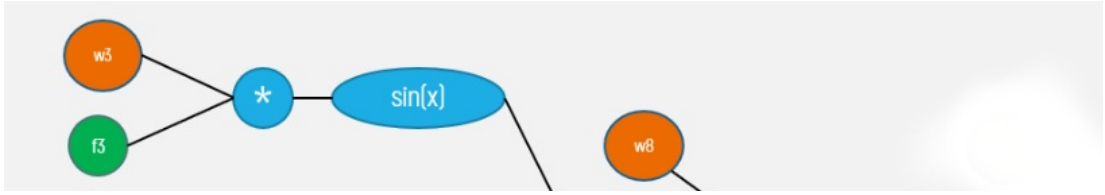
- **Write two functions**
  - **Forward propagation(Write your code in def forward_propagation())**

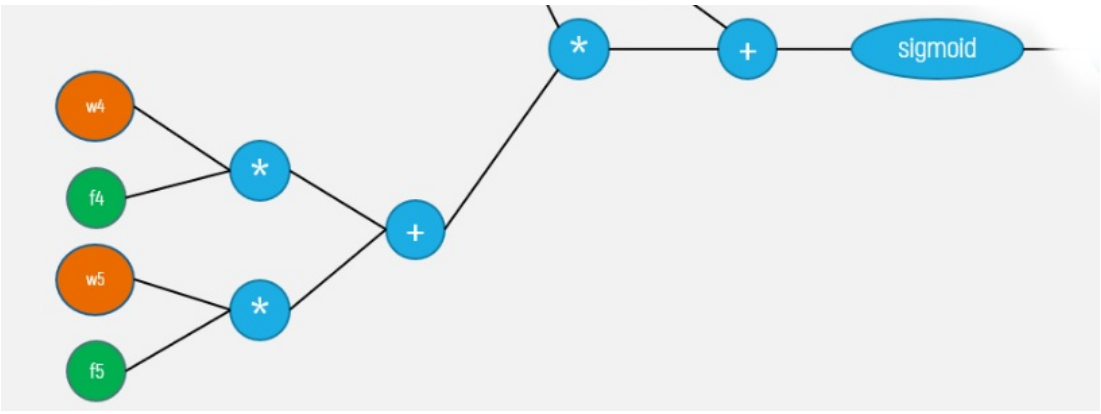
    For easy debugging, we will break the computational graph into 3 parts.

    Part 1

    Part 2

    Part 3





```
def forward_propagation(X, y, W):

 # X: input data point, note that in this assignment you are having 5-d dat
a points
 # y: output varible
 # W: weight array, its of length 9, W[0] corresponds to w1 in graph, W[1]
corresponds to w2 in graph,
         ..., W[8] corresponds to w9 in graph.
 # you have to return the following variables
 # exp= part1 (compute the forward propagation until exp and then store
the values in exp)
 # tanh =part2(compute the forward propagation until tanh and then store th
e values in tanh)
 # sig = part3(compute the forward propagation until sigmoid and then store
the values in sig)
 # now compute remaining values from computional graph and get y'
 # write code to compute the value of L=(y-y')^2
 # compute derivative of L  w.r.to Y' and store it in dl
 # Create a dictionary to store all the intermediate values
 # store L, exp,tanh,sig,dl variables

 return (dictionary, which you might need to use for back propagation)
```

- Backward propagation(Write your code in def backward_propagation())

```
def backward_propagation(L, W,dictionary):

 # L: the loss we calculated for the current point
 # dictionary: the outputs of the forward_propagation() function
 # write code to compute the gradients of each weight [w1,w2,w3,...,w9]
 # Hint: you can use dict type to store the required variables
 # return dW, dW is a dictionary with gradients of all the weights

 return dW
```

Task 1

Forward propagation

In [4]:

```
def sigmoid(z):
    '''In this function, we will compute the sigmoid(z)'''

    # we can use this function in forward and backward propagation

    return 1/(1 + np.exp(-z))

def forward_propagation(x, y, w):

    t1=w[0]*x[0]
    t2=w[1]*x[1]
    t3=t1+t2
    t4=t3*t3

    t5=t4+w[5]
    exp=np.exp(t5)
    t7=exp+w[6]
    tanh=np.tanh(t7)

    t9=w[2]*x[2]
    t10=np.sin(t9)

    t11=w[3]*x[3]
    t12=w[4]*x[4]
    t13=t11+t12

    t14=t13*t10

    t15=t14+w[7]

    sig=sigmoid(t15)

    t16=sig*w[8]

    y_hat= t16+tanh

    L=np.square(y-y_hat)
    dl=-2*(y-y_hat)

    dic={
        'exp':exp,
        'sigmoid':sig,
        'tanh':tanh,
        'loss':L,
        'dy_pr':dl,
        'sin':t10,
        'cos':np.cos(t9)

    }

    return dic
```

Grader function - 1

In [5]:
